

## ***Appendix A: Data on China's Labor Markets***

A major difficulty in analyzing China's labor markets is that China lacks a labor force survey that covers the population. In the past when the communes employed those with rural *hukou* and the state sector employed those with urban *hukou*, aggregated employment and earnings statistics were collected via administrative reporting systems. However, economic reform changed employment institutions and thus substantially weakened data collection coverage. Although the *Statistical Yearbooks* still publish aggregated data, the National Bureau of Statistics relies heavily on rules of thumb and assumptions to put data together, and every five to ten years, the population survey or census data are used to make adjustments. Different *Yearbooks*, therefore, often provide different figures and trends.

At the micro level, China's National Bureau of Statistics conducts two major household surveys that are intended to be nationally representative: the Rural Household Survey (RHS) and the Urban Household Survey (UHS). The division is based on *hukou* status and aimed at collecting detailed income and expenditure information. The former has only been made available to a limited number of academics for a few years and a few provinces at a time; while the latter do not include migrant workers in cities. There are also censuses and population survey data, which normally do not have earnings, or detailed labor market information. Thus, labor market analysis based on official data is limited.

There are essentially four major non-official household surveys that have been used for labor market research. First, the China Income Project Surveys (CHIPs) is a series of repeated cross-sections for year 1988, 1995, 1999 (for six provinces only), and 2002. It covers around 15,000 rural and urban households in 11 provinces and in 2002 it also includes 2000 non-random sampling of migrant households. CHIPs essentially use the NBS' RHS and UHS survey samples and the surveys were conducted by NBS. Second, the China Health and Nutrition Survey (CHNS) offers panel data for 1989, 1991, 1993, 1997, 2000, 2002, 2004, and 2006. It covers seven provinces and total of 4400 households, including rural and urban samples, but without migrants. Third, the China Urban Labor Survey (CULS) has repeated cross-sections for 2001, 2005 and 2010. It covers five cities with less than 3000 households, including urban and migrant households. These surveys either ignore or do not have a representative migrant sample (Gong, Kong, Li, and Meng, 2008).

Fourth, in 2008 the Rural-Urban Migration in China and Indonesia (RUMiCI) project was initiated, which comprises three samples in China: 8,000 rural *hukou* households, 5,000 urban *hukou* households, and 5,000 migrant households. The surveys of urban and migrant households are conducted in the same 15 cities, while the rural household surveys are conducted in nine provinces where these 15 cities located. Differing from the previous household surveys, the RUMiCI migrant survey is based on a sampling

frame constructed by the RUMiCI team which conducted census of migrants via workplaces in the survey cities. It closely resembles the labor market characteristics of migrants in the 1% Population Survey of 2005. For detailed information on RUMiCI sampling, sample size, and other related issues, see Gong et. al., (2008); or <http://cbe.anu.edu.au/schools/eco/rumici/>.
